Sometimes, mutation in a chromosomal gene of pathogenic bacteria can confer resistance. In other cases, bacteria have "resistance genes," which code for enzymes that specifically destroy or otherwise hinder the effectiveness of certain antibiotics. Such resistance genes are carried by plasmids known as R plasmids (R for resistance).

positive cells. Bacteria treated with these antibiotics become osmotically sensitive and lyse in hypotonic solutions, including human body fluids. Most Archaea have a paracrystalline surface layer (called an S layer), composed of protein or glycoprotein, that performs the same general functions as a Bacterial cell wall.

In the past, archaea were classified as bacteria and were called archaeobacteria. But it was discovered that archaea have a distinct evolutionary history and biochemistry compared with bacteria. The similarities are that archaea and eubacteria are prokaryotes "single-celled organisms that do not have a nucleus or organelles.

Mapping of bacteria and archaea Maps of the 20 most representative phyla, identified in Fig. 2, were drawn by applying a geostatistical approach based on their relative abundance (Fig. 4, fig. S2, and table S2). In the linear models used for interpolation,  $\beta$  ranged from 0.04 to 0.29, revealing spatial R structuring depending on the phylum.

Salt-tolerant archaea (the Haloarchaea) use sunlight as an energy source, and other species of archaea fix carbon, but unlike plants and cyanobacteria, no known species of archaea does both. Archaea reproduce asexually by binary fission, fragmentation, or budding; unlike bacteria and eukaryotes, no known species forms spores.
